OBSERVATIONS 1995

YEARBOOK No 37

BERGEN 1997

N O R W A Y

GENERAL INFORMATION AND PERSONNEL

The Magnetic Station at Dombås is operated by the University of Bergen.
All correspondence or inquiries can be sent to:

University of Bergen
Institute of Solid Earth Physics
Geomagnetism
Allégt. 41
N-5007 Bergen, Norway

The altitude of the observatory is 660 m above sea level, and its geographical coordinates are:
 $\phi = 62^\circ 04'.4N$, $\lambda = 09^\circ 07'0E$. The dipole coordinates (North geomagnetic pole at $\phi = 79^\circ N$, $\lambda = 289^\circ E$) are: $\Phi = 62.0^\circ N$, $\Lambda = 101.0^\circ E$. The IAGA-code is DOB.

Martin Berg is in charge of the daily management of the observatory and the absolute measurements.

INSTRUMENTATION

The observatory operates two digital variometer systems on a permanent basis.

The first digital system, consist of a triaxial fluxgate magnetometer with about 0.5 nT resolution and axes oriented toward magnetic north (H), magnetic east (D) and downwards (Z) and a Geometrics Basestation proton magnetometer with 1 nT resolution. The analog outputs are digitized and sampled every 20 second by an Opto 22 logger. A detailed presentation and discussion of this instrumentation can be found in the yearbook for 1991, in the paragraph: "The digital variometer system". From the end of May, a new version, LC4 with a daughter card EX2 replaced the LC2, giving nearly twice as large storing capacity of the recorded data during power breaks, an extra serial port and a 24-line parallel port. On November 8, the EDA FM-100B fluxgate was replaced by a Danish fluxgate (FGE-89D, made by DMI) with suspended sensors. More information can be found in the paragraph: " The new primary fluxgate".

The second digital system consists of another triaxial fluxgate (FG-90B), likewise with sensors oriented toward magnetic north, magnetic east and downwards. A display gives the output from the sensors with 0.1nT resolution, and the data are logged with 0.12 nT/bit. An Elsec 820 proton magnetometer provides total field values with 0.1 nT resolution, and the data are sampled every 20 second by an Oettle & Reichler logger using the OS-9 operating system. An Optocom 19200 baud modem connects the system to the computers at the Institute. More information is available in the yearbook for 1994.

Time is in general read from the respective CPU-clocks. The LC2 clock had a slow drift and in connection with the upgrading of the logger, a radio clock (DCF-77) with digital output was installed. The recorded time is now rarely in error with more than ± 1 sec. More information can be found in the paragraph: "The new time control".

ABSOLUTE MEASUREMENTS

For absolute observations we use a DI-flux with the sensor mounted on a Zeiss 010B theodolite and the Elsec 820 proton magnetometer.

THE NEW PRIMARY FLUXGATE

It has been evident from the variation of the base-line values in D for both our fluxgates that the pillars are not stable. We have run tests to monitor the change in the leveling of the pillar-tops on a weekly basis over several years, and found a clear relation to the base-line changes in D.

In addition it is well known that the fluxgates which originally were made for field work as pure variometers did not comply with the modern standards for mechanical and thermal stability of the mounting of sensors and compensation coils, and insensitivity of the electronics to temperature changes.

A Danish triaxial fluxgate magnetometer, model FGE-89D, serial no. 134 and made by the Danish Meteorological Institute, therefore replaced the old EDA magnetometer on November 8. The new magnetometer is of a type where the sensor mounting, a marble cube, is suspended by a set of two crossed bands, made of phosphor-bronze. This gives a stable orientation without tilting effects. The suspension is damped with the help of a special device mounted beneath the cube and immersed in silicone oil. Each sensor is fixed inside a quartz tube with the compensation coil wound around the tube. The tubes are firmly fixed in grooves, orthogonal to each other. The electronic box is almost nonmagnetic, so both sensors and electronics can then be placed in the same room with stable temperature.

The sensor axes are toward magnetic north (H), magnetic east (D) and downwards (Z). The resolution has been set to 100 nT/V, this gives a logged dynamic range of ± 1000 nT.

THE NEW TIME CONTROL

Clocks which receive the German atomic time signal from Mainflingen (DCF-77) are commercially available, although not many have a digital output. From Danbit we obtained a unit made for PCs. The unit was mounted outside on the wall of the variometerhouse and

connected to the parallel port of the Opto logger.

The unit with additional electronics converts the radio signal from the atomic clock to a sequence of TTL compatible voltage pulses, one pulse every second where the length signifies "1" (200 ms) or "0" (100 ms). No pulse in the 59th second in the minute serves as mark. The sequence of pulses represents BCD coded characters and parity checks.

In order to achieve a complete set of timecode, it is necessary to log the sequence of pulses for maybe 2 minutes, as one needs the mark to synchronize the logging. This was not acceptable, as it meant that no variometer records would be obtained during the period. Instead a subroutine was written for the logging program which when called after the 40th second in a minute, looks for the mark only and notes the value of current second of the logger time. In case the clock is running ahead, the subroutine will wait for the mark for about 10 seconds into the next minute before resuming the ordinary logging of the variometers.

This routine is called twice during night, and it will run for 5 minutes each time. In case a valid sequence of pulses has been received and all 5 logged values of the current second are equal, the true value of the current second is then put back into the appropriate hardware address of the clock. If not, no correction is made.

In order to monitor the time correction, the value of the current second replaces the logged sensor temperature for that hour. Direct checking of the logger time is also done at times. Although the procedure will not handle situations with erroneous date, hours and minutes, and large errors in the second, this simple routine has kept the logging time correct to the nearest second.

THE NEW METHOD FOR DERIVATION OF K-INDICES

The cessation of the photographic recordings demanded a change in the routines for K-index derivation. The simplest change would be to continue with scaling by hand, but now from daily plots of the digital recordings. It was however, decided to introduce a numerical algorithm to reduce the amount of work spent with the data.

Of the 5 algorithms acknowledged by IAGA Working Group V (ref IAGA News No 32, 1993), the "FMI" method was chosen. The algorithm is developed at the Finnish Meteorological Institute by Lasse Hakkinen. It uses an iterative procedure in combination with a simple Fourier analysis, based on the data for the current day and the day before and after, to estimate the background smooth variation. This variation is adjusted for the local solar time of the observatory and is based on the expected difference of the curve between day and night and rough estimates of the current magnetic activity. Both horizontal components are used for picking out the maximum range for each 3 hour interval of the current day.

The Fortran version of the program has been translated from ANSI C and corrected by Phil McFadden of AGSO. The program files were obtained from the ISGI Publication Office, and adapted to our data format and sampling rate. As input to the program we use all the data-samples from the second system so that the K-indices is available at the end of each month.

A comparison of the old and the new method for some selected months gave the same K-index in 75% of the intervals, for 15% the new values were too high and 10 % too small by 1 unit. Occasionally they differed by 2 units.

DIARY FOR 1995

The photographic La Cour recorder was stopped for daily use in the beginning of January, such ending a period of regular recordings since 1952. During the year, magnetograms have only been produced during absolute observations as an additional check.

There are two major gaps in the data. The first between February 11 and 13 is caused by the circuit breaker which cut off the power to both variometer systems.

The circuit breaker was replaced in March by a device which only warns about a fault in the earthing.

On July 14, a severe lightning discharge damaged the fluxgate (FG-90B) of the second system and the PC for the first system failed to restart, giving a gap in the data until the 17. (Note that both periods are during weekends). The magnetometer had to be sent to Tromsø for repairs, and was back in operation August 31.

Again the PC for the first system stopped on July 31, and had to be restarted on August 7. By pure chance, it had been decided to restart the La Cour recorder the same day, so this stop did not give a gap.

NOTES ON THE TABLES

Table 1 gives the adopted scale values for D, H and Z, for the three variometer systems. Tables 2-4 gives adopted baseline values. Table 5 gives monthly and annual means for all days and for the 5 international quiet and disturbed days, while Table 6 gives the annual means (all days) from 1952 up to the present year. The following tables give the mean values of D, H and Z for hourly, daily and monthly intervals. Note that positive values in the D-tables mean a more westerly declination than the heading value. In addition is given the mean daily variation for each month, calculated separately for all days (M), 5 quiet days (MQ) and disturbed days (MD). The averages for the hourly values are centered at half-hours. Universal time (GMT) is used consistently.

The final table gives the three-hour-range indices K and daily sums of K, computed from data from the second variometer by the "FMI"-method, or by scaling from magnetograms .
